Synopsis: I have been developing a tool called sbuilder, which produces formal models in TLA+ language representing "business IT" systems, i.e. application with interfaces, persistent state and service semantics between these two.

The idea is to use a formal model to generate "virtual system tests". The work flow:

- 1) Create a formal model + with correctness invariant (assisted by sbuilder translation)
 - 2) Run model checking on formal model in the "usual" way
 - 3) Run model checking using a configuration, which produces a counter example, which represent execution we would like to test the system with.
 - 4) Parse the counter example and extract interface calls steps: a) state of the formal model before interface call, b) formal model parameter binding to the interface call, c) formal model interface response message, d) formal model state after the call
 - 5) iterate each interface step in the trace and execute it as unit test
- a) map formal model before

GUIDELINES

state to implementation state && init SUT with that state b) map formal model interface parameter bindings to a request in implementation state && send that req. msg to SUT c) receive response msg from SUT and compare it with formal model response message mapped to implementation state d) map formal model after state top implementation && check SUT state 6) Interpret the aggregate result of executing individual unit tests as a virtual system test

As the result: - expect saving in "virtual" system testing, because executing unit test is considerable easier than trying to manage execution of a system test as a single unit - formal model and implementation conformance increased

▼ Your work seems very interesting. Even though the idea of generating tests from model-checker counterexamples is not new, it's great to see it implemented using TLA⁺. However, your text is very hard to follow. It employs both too many buzzwords, and has too little in way of explanation. If you can write in greater detail it will be easier to appreciate your work.

▼ I know I have trouble in expressing my thoughts (failing to balance between being too verbose and too succinct ;) - especially, because, I confess, I do not fully understand the problem I am trying to solve with this sbuilder stuff.

However, yet another try:

<https://jarjuk.wordpress.com/2018/03/12/simple-sdd-demo/>

And, sure enough - it also ends with more questions: This blog post has used "Simple 'Specification Driven Development' Demo" to point out several issues, which may rise, when trying to apply Specification Driven Development for real cases. It is left for further blog post(s) to cover, how to solve these issues.

▼ To create counter examples, referenced above, sbuilder offers "possibility" operators, which are implemented on top of TLA+tools extension feature. A possibility operator translates to an extension module, which extends base module holding formal model of the application. The extension module

CSS via [/r/Structura](#) by [/u/Cereal_Addict](#)

requires negation of "possibility" operator to hold universally. In step 2 above, we would be model checking using the base module, and in step 3, using the extension module. Refer to <https://jarjuk.wordpress.com/2017/12/06/sbuilder-wallet-1/#orgheadline3> blog entry for more details.
